AUTOMATED FINDER FOR THE CRITICAL CONDITION ON THE
LINEAR STABILITY OF FLUID MOTIONS

March 1990

Kaoru FUJIMURA

JAERI-Mレポートは、日本原子力研究所が不定期に公刊している研究報告書です。
入手の問合わせは、日本原子力研究所技術情報部情報資料課（〒319-11茨城県那珂郡東海村）あて、お申しこしください。なお、このほかに財団法人原子力弘済会資料センター（〒319-11茨城県那珂郡東海村日本原子力研究所内）で複写による実費頒布をおこなっております。

JAERI-M reports are issued irregularly.

Inquiries about availability of the reports should be addressed to Information Division, Department of Technical Information, Japan Atomic Energy Research Institute, Tokai-mura, Naka-gun, Ibaraki-ken 319-11, Japan.

Automated Finder for the Critical Condition
on the Linear Stability of Fluid Motions

Kaoru FUJIMURA

High Temperature Engineering Department
Tokai Research Establishment
Japan Atomic Energy Research Institute
Tokai-mura, Naka-gun, Ibaraki-ken

(Received February 21, 1990)

An automated finder routine for the critical condition on the linear stability of fluid motions is proposed. The Newton-Raphson method was utilized for an iteration to solve nonlinear eigenvalue problems appeared in the analysis. The routine was applied to linear stability problem of a free convection between vertical parallel plates with different non-uniform temperatures as well as a plane Poiseuille flow. An efficiency of the finder routine is demonstrated for several parameter sets, numerically.

1. INTRODUCTION

An evaluation of the critical condition is the main objective in linear stability analyses for fluid motions. The governing disturbance equation usually involves the Orr-Sommerfeld equation in it. The latter equation has the form of

$$i\alpha(U-c)(\phi''-\alpha^2\phi)-U''\phi-R^{-1}(\phi^{iv}-2\alpha^2\phi''+\alpha^4\phi)=0, \quad (1)$$

where i is the imaginary unit, U is a basic flow as a function of transverse co-ordinate y ($U=1-y^2$ for plane Poiseuille flow, $U=y$ for plane Couette flow, and so on), c is a complex phase velocity, α is a wavenumber, ϕ is an amplitude function of y for a normal mode, R is the Reynolds number, and the prime denotes a differentiation with respect to y . The boundary conditions for ϕ are imposed as

$$\phi(\pm 1)=\phi'(\pm 1)=0. \quad (2)$$

Equations (1) and (2) provide an eigenvalue problem. The complex phase velocity c is determined as the eigenvalue for prescribed values of (α, R) . Linear growth rate is defined by αc_i where c_i is the imaginary part of c while a phase velocity is defined by c_r , the real part of c . If $\alpha c_i=0$, the flow is neutrally stable. The critical condition in the parameter space (α, R) is determined as a pair of the minimum Reynolds number R and corresponding α satisfying that $\alpha c_i=0$, $dR/d\alpha=0$, and $d^2R/d\alpha^2>0$. If the neutral stability curve is double nosed as was obtained in unstably stratified shear flows¹ for instance, the last condition is necessary. If the neutral curve has single nose, on the other hand, the critical condition is given by only two simple conditions $\alpha c_i=0$ and $dR/d\alpha=0$. We consider the latter case here.

Consider a situation $c_r=0$ and $c_i=0$. This is the case for stationary disturbances in plane Couette flow, free shear layer with anti-symmetric velocity profile, and a free convection between vertical parallel plates with different temperatures. Then the equation (1) is simplified as

$$i\alpha U(\phi''-\alpha^2\phi)-U''\phi-R^{-1}(\phi^{iv}-2\alpha^2\phi''+\alpha^4\phi)=0, \quad (3)$$

for the neutral state. The neutral Reynolds number for some specific α can thus be obtained from (3) as an eigenvalue and depicting the neutral stability curve is a simple task. The critical condition for this case is thereafter determined numerically.

The situation $c_r=0$ and $c_i=0$, however, is not the case in general. Indeed, all the traveling wave disturbances have non-zero c_r even in the plane Couette flow. We have to solve (1) and obtain the complex phase velocity, at first. The neutral condition is determined thereafter, and the critical condition is finally calculated. Numerical errors will be accumulated during the numerical determination of the critical condition.

By the way, a solution of the Orr-Sommerfeld equation is known to become singular as $R \rightarrow \infty$ in the critical layer.² Behavior of $\phi(y)$ across the critical layer is so rapidly changing that highly accurate numerical treatment is required to handle this equation. Recent progress in the numerical computation guarantees that an expansion of $\phi(y)$ in Chebyshev polynomials $T_n(y)$ or Legendre polynomials $P_n(y)$ provides reliable numerical accuracy.^{2,3} The accuracy kept in the expansion in these orthogonal Jacobian polynomials should also be maintained in determining the critical condition.

The objective of the present report is to establish these determination process of the critical condition with extremely high accuracy. We consider about more complicated system than the Orr-Sommerfeld problem : linear stability of a free convection between vertical parallel plates with different non-uniform temperatures. Governing equations are composed of an equation for velocity disturbance and an equation for temperature disturbance. The two equations are coupled through a buoyancy term. The equation for the velocity disturbance involves the Orr-Sommerfeld equation in it.

We describe the way to find the critical condition in §2 and give a brief guide about the numerical program in §3. The program list is given in §4 and sample numerical results are presented in §5.

2. PROCEDURE TO FIND THE CRITICAL CONDITION

Let us briefly give an idea to get the critical condition, at first. The critical state is a special state satisfying $\partial G/\partial \alpha = 0$ among the neutral states. Thus the neutral states for some specific values of α are evaluated at first in ordinary critical-condition finder routine. Note that determination of the neutral state requires several iterations, N_1 say, at least. Then the finding of the critical condition by making use of the stability data for the neutral disturbances requires another several iterations, N_2 say, at least. This means that $N_1 \times N_2$ iterations are necessary in order to determine the critical condition. If we assume the critical conditions $c_i=0$ and $\partial G/\partial \alpha=0$ from the very beginning, the number of iterations will be reduced substantially. The former condition can be imposed if we split the disturbance equation in the real and the imaginary parts while the latter condition can be imposed if we differentiate the disturbance equation with respect to α . In the following, we propose such an efficient routine to find the critical condition.

Start from non-dimensionalized disturbance equations of the form of

$$i\alpha(W-c)S\phi - i\alpha W''\phi - G^{-1}S^2\phi + G^{-1}D\theta = 0, \tag{4}$$

$$i\alpha(W-c)\theta - (GP)^{-1}S\theta + i\alpha T'\phi - \beta D\phi = 0, \tag{5}$$

where α is a wavenumber, c is a complex phase velocity, ϕ is an amplitude function of the normal mode for velocity disturbance, θ is an amplitude function of the normal mode for temperature disturbance, G is the Grashof number, P is the Prandtl number, β is a non-dimensional temperature gradient in the vertical (z) direction, $D \equiv d/dx$, and $S \equiv D^2 - \alpha^2$. Homogeneous boundary conditions are imposed at $x = \pm 1$: $\phi(\pm 1) = \phi'(\pm 1) = \theta(\pm 1) = 0$. The basic fields W and T are functions of x and β as

$$W = -\frac{\text{Im } f}{2m^2}, \quad T = \text{Re } f, \tag{6,7}$$

where $f(x, m) = \frac{\sinh[(1+i)mx]}{\sinh[(1+i)m]}$, and $m = (\frac{\beta GP}{4})^{1/4}$.^{4,5}

Consider the neutral state. The imaginary part of c then vanishes. Denote the real part of c as c for simplicity and without any confusion. Decompose (4) and (5) into the real and the

imaginary parts of the form of

$$-\alpha(W-c)S\phi_i+\alpha W''\phi_r-G^{-1}S^2\phi_r+G^{-1}D\theta_r=0, \quad (8)$$

$$\alpha(W-c)S\phi_r-\alpha W''\phi_i-G^{-1}S^2\phi_i+G^{-1}D\theta_i=0, \quad (9)$$

$$-\alpha(W-c)\theta_i-(GP)^{-1}S\theta_r-\alpha T'\phi_r-4m^4(GP)^{-1}D\phi_r=0, \quad (10)$$

$$\alpha(W-c)\theta_r-(GP)^{-1}S\theta_i+\alpha T'\phi_i-4m^4(GP)^{-1}D\phi_i=0. \quad (11)$$

Split ϕ_r , ϕ_i , θ_r , θ_i , c , and G into the old values and new corrections as

$$\phi_r \rightarrow \bar{\Phi}_r + \phi_r, \quad \phi_i \rightarrow \bar{\Phi}_i + \phi_i, \quad \theta_r \rightarrow \bar{\Theta}_r + \theta_r, \quad \theta_i \rightarrow \bar{\Theta}_i + \theta_i, \quad c \rightarrow C + c, \quad \text{and} \quad G^{-1} \rightarrow G^{-1} + g^{-1}.$$

Substitute these expression into (8)-(11) and neglect the nonlinear terms with respect to the correction components. We then have the following linearized equations :

$$\begin{aligned} -\alpha(W-C)S\phi_i+\alpha W''\phi_r-G^{-1}S^2\phi_r+G^{-1}D\theta_r+\alpha cS\bar{\Phi}_i-g^{-1}S^2\bar{\Phi}_r+g^{-1}D\bar{\Theta}_r \\ =-[-\alpha(W-C)S\phi_i+\alpha W''\phi_r-G^{-1}S^2\bar{\Phi}_r+G^{-1}D\bar{\Theta}_r], \end{aligned} \quad (12)$$

$$\begin{aligned} \alpha(W-C)S\phi_r-\alpha W''\phi_i-G^{-1}S^2\phi_i+G^{-1}D\theta_i-\alpha cS\bar{\Phi}_r-g^{-1}S^2\bar{\Phi}_i+g^{-1}D\bar{\Theta}_i \\ =-[\alpha(W-C)S\phi_r-\alpha W''\phi_i-G^{-1}S^2\bar{\Phi}_i+G^{-1}D\bar{\Theta}_i], \end{aligned} \quad (13)$$

$$\begin{aligned} -\alpha(W-C)\theta_i-(GP)^{-1}S\theta_r-\alpha T'\phi_r-4m^4(GP)^{-1}D\phi_r+\alpha c\bar{\Theta}_i-(gP)^{-1}S\bar{\Theta}_r-4m^4(gP)^{-1}D\bar{\Phi}_r \\ =-[-\alpha(W-C)\theta_i-(GP)^{-1}S\theta_r-\alpha T'\phi_r-4m^4(GP)^{-1}D\bar{\Phi}_r], \end{aligned} \quad (14)$$

$$\begin{aligned} \alpha(W-C)\theta_r-(GP)^{-1}S\theta_i+\alpha T'\phi_i-4m^4(GP)^{-1}D\phi_i-\alpha c\bar{\Theta}_r-(gP)^{-1}S\bar{\Theta}_i-4m^4(gP)^{-1}D\bar{\Phi}_i \\ =-[\alpha(W-C)\theta_r-(GP)^{-1}S\theta_i+\alpha T'\phi_i-4m^4(GP)^{-1}D\bar{\Phi}_i]. \end{aligned} \quad (15)$$

The above procedure is not new but the Newton-Raphson method itself.

Expand $\bar{\Phi}_r$, $\bar{\Phi}_i$, $\bar{\Theta}_r$, $\bar{\Theta}_i$, ϕ_r , ϕ_i , θ_r , and θ_i in Chebyshev polynomials as

$$[\bar{\Phi}_r, \bar{\Phi}_i, \bar{\Theta}_r, \bar{\Theta}_i]^T = \sum_{n=0}^N [\bar{\Phi}_r^{(n)}, \bar{\Phi}_i^{(n)}, \bar{\Theta}_r^{(n)}, \bar{\Theta}_i^{(n)}]^T (1-x^2)^2 T_n(x), \quad (16)$$

$$[\phi_r, \phi_i, \theta_r, \theta_i]^T = \sum_{n=0}^N [\phi_r^{(n)}, \phi_i^{(n)}, \theta_r^{(n)}, \theta_i^{(n)}]^T (1-x^2) T_n(x). \quad (17)$$

We introduce here a normalization condition as $\bar{\Phi}_r^{(0)}=1$, $\phi_r^{(0)}=\bar{\Phi}_i^{(0)}=\bar{\Theta}_i^{(0)}=0$. Substituting (16) and (17) into (11)-(15) and making use of the collocation method, we obtain coupled algebraic equation of the form of

$$\mathbf{Bx} = \mathbf{b}, \quad (18)$$

where \mathbf{B} is a $4(N+1) \times 4(N+1)$ matrix, \mathbf{x} and \mathbf{b} are $4(N+1)$ -vectors, and \mathbf{x} is expressed by

$$\mathbf{x} = [c, \phi_r^{(1)}, \phi_r^{(2)}, \dots, \phi_r^{(N)}, g^{-1}, \phi_i^{(1)}, \phi_i^{(2)}, \dots, \phi_i^{(N)}, \theta_r^{(0)}, \theta_r^{(1)}, \dots, \theta_r^{(N)}, \theta_i^{(0)}, \theta_i^{(1)}, \dots, \theta_i^{(N)}]^T. \quad (19)$$

Eq. (18) is readily solved.

This is the explanation about how to find the neutral Grashof number, phase velocity, and corresponding eigenfunction for given values of α . In order to attack the critical condition, we need initial guesses of $\partial\phi/\partial\alpha$ and $\partial c/\partial\alpha$ for the neutral modes as will be shown below. The above procedure is used for this purpose.

Let us now proceed to the next step : determination of the critical condition. The critical condition is considered to be given by $dG/d\alpha=0$ and $d^2G/d\alpha^2>0$. In the following, we neglect the second condition. In order to impose the first condition, we differentiate (4) and (5) with respect to α as

$$[i(W-c)S - i\alpha c_\alpha S + i\alpha(W-c)S_\alpha - iW'' - G^{-1}_\alpha S^2 - G^{-1}S^2_\alpha] \phi + G^{-1}_\alpha D\theta + [i\alpha(W-c)S - i\alpha W'' - G^{-1}S^2] \phi_\alpha + G^{-1}D\theta_\alpha = 0, \quad (20)$$

$$[i(W-c) - i\alpha c_\alpha - P^{-1}G^{-1}_\alpha S - (GP)^{-1}S_\alpha] \theta + iT'\phi + [i\alpha(W-c) - (GP)^{-1}S] \theta_\alpha + i\alpha T'\phi_\alpha - 4m^4(GP)^{-1}D\phi_\alpha = 0, \quad (21)$$

where suffix α denotes the differentiation with respect to α , $S_\alpha = -2\alpha$, and $S^2_\alpha = -4\alpha D^2 + 4\alpha^3$. Now we impose the condition $G^{-1}_\alpha = 0$. Decompose (20) and (21) into real and imaginary part of the form of

$$-(W-c)S\phi_1 + \alpha c_\alpha S\phi_1 - \alpha(W-c)S_\alpha\phi_1 + W''\phi_1 - G^{-1}S^2_\alpha\phi_1 - \alpha(W-c)S\phi_{\alpha 1} + \alpha W''\phi_{\alpha 1} - G^{-1}S^2\phi_{\alpha 1} + G^{-1}D\theta_{\alpha r} = 0, \quad (22)$$

$$(W-c)S\phi_i - \alpha c_\alpha S\phi_i + \alpha(W-c)S_\alpha\phi_i - W''\phi_i - G^{-1}S^2_\alpha\phi_i + \alpha(W-c)S\phi_{\alpha i} - \alpha W''\phi_{\alpha i} - G^{-1}S^2\phi_{\alpha i} + G^{-1}D\theta_{\alpha i} = 0, \quad (23)$$

$$\begin{aligned}
 &-(W-c)\theta_i+\alpha c_\alpha\theta_i-(GP)^{-1}S_\alpha\theta_r-T'\phi_i-\alpha(W-c)\theta_{\alpha i}-(GP)^{-1}S\theta_{\alpha r}-\alpha T'\phi_{\alpha i} \\
 &\quad -4m^4(GP)^{-1}D\phi_{\alpha r}=0, \tag{24}
 \end{aligned}$$

$$\begin{aligned}
 &(W-c)\theta_r-\alpha c_\alpha\theta_r-(GP)^{-1}S_\alpha\theta_i+T'\phi_r+\alpha(w-c)\theta_{\alpha r}-(GP)^{-1}S\theta_{\alpha i}+\alpha T'\phi_{\alpha r} \\
 &\quad -4m^4(GP)^{-1}D\phi_{\alpha i}=0. \tag{25}
 \end{aligned}$$

Split the variables in (22)–(25) into the old values and corrections as $\phi_{\alpha r} \rightarrow \Phi_{\alpha r} + \phi_{\alpha r}$, $\phi_{\alpha i} \rightarrow \Phi_{\alpha i} + \phi_{\alpha i}$, $\theta_{\alpha r} \rightarrow \Theta_{\alpha r} + \theta_{\alpha r}$, $\theta_{\alpha i} \rightarrow \Theta_{\alpha i} + \theta_{\alpha i}$, $c_\alpha \rightarrow C_\alpha + c_\alpha$, and $\alpha \rightarrow A + \alpha$. Then the Newton-Raphson procedure gives us the following equations for the correction terms :

$$\begin{aligned}
 &-(W-C)S\phi_i+AC_\alpha S\phi_i-A(W-C)S_\alpha\phi_i+W''\phi_i-G^{-1}S^2_\alpha\phi_i-A(W-C)S\phi_{\alpha i}+AW''\phi_{\alpha i} \\
 &\quad -G^{-1}S^2\phi_{\alpha r}+G^{-1}D\theta_{\alpha r}+cS\phi_i+\alpha C_\alpha S\phi_i+Ac_\alpha S\phi_i+\alpha(W-C)S_\alpha\phi_i \\
 &\quad +AcS_\alpha\phi_i-g^{-1}S^2_\alpha\phi_r+AcS\phi_{\alpha i}+\alpha(W-C)S\phi_{\alpha i}+\alpha W''\phi_{\alpha i}-g^{-1}S^2\phi_{\alpha r} \\
 &\quad +g^{-1}D\theta_{\alpha r}-\alpha(W-C)S_\alpha\phi_i+\alpha AC_\alpha S_\alpha\phi_i-\alpha A(W-c)S_{\alpha\alpha}\phi_i-G^{-1}\alpha S^2_{\alpha\alpha}\phi_r \\
 &\quad -\alpha A(W-C)S_\alpha\phi_{\alpha i}-G^{-1}\alpha S^2_\alpha\phi_{\alpha r} \\
 &= [-(W-C)S\phi_i+AC_\alpha S\phi_i-A(W-C)S_\alpha\phi_i+W''\phi_i-G^{-1}S^2_\alpha\phi_i \\
 &\quad -A(W-C)S\phi_{\alpha i}+AW''\phi_{\alpha i}-G^{-1}S^2\phi_{\alpha r}+G^{-1}D\theta_{\alpha r}], \tag{26}
 \end{aligned}$$

$$\begin{aligned}
 &(W-C)S\phi_r-AC_\alpha S\phi_r+A(W-C)S_\alpha\phi_r-W''\phi_r-G^{-1}S^2_\alpha\phi_r+A(W-C)S\phi_{\alpha r}-AW''\phi_{\alpha r} \\
 &\quad -G^{-1}S^2\phi_{\alpha i}+G^{-1}D\theta_{\alpha i}-cS\phi_r-\alpha C_\alpha S\phi_r-Ac_\alpha S\phi_r-\alpha(W-C)S_\alpha\phi_r \\
 &\quad -AcS_\alpha\phi_r-g^{-1}S^2_\alpha\phi_i-AcS\phi_{\alpha r}-\alpha(W-C)S\phi_{\alpha r}-\alpha W''\phi_{\alpha r}-g^{-1}S^2\phi_{\alpha i} \\
 &\quad +g^{-1}D\theta_{\alpha i}+\alpha(W-C)S_\alpha\phi_r-\alpha AC_\alpha S_\alpha\phi_r+\alpha A(W-c)S_{\alpha\alpha}\phi_r-G^{-1}\alpha S^2_{\alpha\alpha}\phi_i \\
 &\quad +\alpha A(W-C)S_\alpha\phi_{\alpha r}-G^{-1}\alpha S^2_\alpha\phi_{\alpha i} \\
 &= [(W-C)S\phi_r-AC_\alpha S\phi_r+A(W-C)S_\alpha\phi_r-W''\phi_r-G^{-1}S^2_\alpha\phi_r \\
 &\quad +A(W-C)S\phi_{\alpha r}-AW''\phi_{\alpha r}-G^{-1}S^2\phi_{\alpha i}+G^{-1}D\theta_{\alpha i}], \tag{27}
 \end{aligned}$$

$$\begin{aligned}
 &-(W-C)\theta_i+AC_\alpha\theta_i-(GP)^{-1}S_\alpha\theta_r-T'\phi_i-A(W-C)\theta_{\alpha i}-(GP)^{-1}S\theta_{\alpha r}-AT'\phi_{\alpha i} \\
 &\quad -4m^4(GP)^{-1}D\phi_{\alpha r}+c\theta_i+\alpha C_\alpha\theta_i+Ac_\alpha\theta_i-(gP)^{-1}S_\alpha\theta_r-(GP)^{-1}\alpha S_{\alpha\alpha}\theta_r \\
 &\quad -\alpha(W-C)\theta_{\alpha i}+Ac\theta_{\alpha i}-(GP)^{-1}S\theta_{\alpha r}-(GP)^{-1}\alpha S_\alpha\theta_{\alpha r}-\alpha T'\phi_{\alpha i}-4m^4(gP)^{-1}D\phi_{\alpha r} \\
 &= [- (W-C)\theta_i+AC_\alpha\theta_i-(GP)^{-1}S_\alpha\theta_r-T'\phi_i-A(W-C)\theta_{\alpha i}-(GP)^{-1}S\theta_{\alpha r} \\
 &\quad -AT'\phi_{\alpha i}-4m^4(GP)^{-1}D\phi_{\alpha r}], \tag{28}
 \end{aligned}$$

$$\begin{aligned}
 & (W-C)\theta_r - AC_\alpha\theta_r - (GP)^{-1}S_\alpha\theta_i + T'\phi_r + A(W-C)\theta_{\alpha r} - (GP)^{-1}S\theta_{\alpha i} + AT'\phi_{\alpha r} \\
 & - 4m^4(GP)^{-1}D\phi_{\alpha i} - c\theta_r - \alpha C_\alpha\theta_r - AC_\alpha\theta_r - (gP)^{-1}S_\alpha\theta_i - (GP)^{-1}\alpha S_{\alpha\alpha}\theta_i \\
 & + \alpha(W-C)\theta_{\alpha r} - Ac\theta_{\alpha r} - (gP)^{-1}S\theta_{\alpha i} - (GP)^{-1}\alpha S_\alpha\theta_{\alpha i} + \alpha T'\phi_{\alpha r} - 4m^4(gP)^{-1}D\phi_{\alpha i} \\
 & = -[(W-C)\theta_r - AC_\alpha\theta_r - (GP)^{-1}S_\alpha\theta_i + T'\phi_r + A(W-C)\theta_{\alpha r} - (GP)^{-1}S\theta_{\alpha i} \\
 & + AT'\phi_{\alpha r} - 4m^4(GP)^{-1}D\phi_{\alpha i}], \tag{29}
 \end{aligned}$$

where $S \equiv D^2 - A^2$, $S_\alpha \equiv -2A$, $S^2_\alpha \equiv -4AD^2 + 4A^3$, $S_{\alpha\alpha} \equiv -2$, and $S^2_{\alpha\alpha} \equiv -4D^2 + 12\alpha^2$. Eqs.

(12)-(15) are altered as

$$\begin{aligned}
 & -A(W-C)S\phi_r + AW''\phi_r - G^{-1}S^2\phi_r + G^{-1}D\theta_r + AcS\phi_r - g^{-1}S^2\phi_r + g^{-1}D\theta_r \\
 & - \alpha(W-C)S\phi_r - \alpha A(W-C)S_\alpha\phi_r + \alpha W''\phi_r - G^{-1}\alpha S^2_\alpha\phi_r \\
 & = -[-\alpha(W-C)S\phi_r + \alpha W''\phi_r - G^{-1}S^2\phi_r + G^{-1}D\theta_r], \tag{30}
 \end{aligned}$$

$$\begin{aligned}
 & A(W-C)S\phi_r - AW''\phi_r - G^{-1}S^2\phi_r + G^{-1}D\theta_r - AcS\phi_r - g^{-1}S^2\phi_r + g^{-1}D\theta_r \\
 & + \alpha(W-C)S\phi_r + \alpha A(W-C)S_\alpha\phi_r - \alpha W''\phi_r - G^{-1}\alpha S^2_\alpha\phi_r \\
 & = -[\alpha(W-C)S\phi_r - \alpha W''\phi_r - G^{-1}S^2\phi_r + G^{-1}D\theta_r]. \tag{31}
 \end{aligned}$$

$$\begin{aligned}
 & -A(W-C)\theta_i - (GP)^{-1}S\theta_r - AT'\phi_i - 4m^4(GP)^{-1}D\phi_r + Ac\theta_i - (gP)^{-1}S\theta_r \\
 & - 4m^4(gP)^{-1}D\phi_r - \alpha(W-C)\theta_i - (GP)^{-1}\alpha S_\alpha\theta_r - \alpha T'\phi_i \\
 & = -[-\alpha(W-C)\theta_i - (GP)^{-1}S\theta_r - \alpha T'\phi_i - 4m^4(GP)^{-1}D\phi_r], \tag{32}
 \end{aligned}$$

$$\begin{aligned}
 & A(W-C)\theta_r - (GP)^{-1}S\theta_i + AT'\phi_r - 4m^4(GP)^{-1}D\phi_i - Ac\theta_r - (gP)^{-1}S\theta_i \\
 & - 4m^4(gP)^{-1}D\phi_i + \alpha(W-C)\theta_r - (GP)^{-1}\alpha S_\alpha\theta_i + \alpha T'\phi_r \\
 & = -[\alpha(W-C)\theta_r - (GP)^{-1}S\theta_i + \alpha T'\phi_r - 4m^4(GP)^{-1}D\phi_i]. \tag{33}
 \end{aligned}$$

$\Phi_{\alpha r}$, $\Phi_{\alpha i}$, $\phi_{\alpha r}$, $\phi_{\alpha i}$, $\Theta_{\alpha r}$, $\Theta_{\alpha i}$, $\theta_{\alpha r}$, $\theta_{\alpha i}$ are again expanded in

$$[\Phi_{\alpha r}, \Phi_{\alpha i}, \phi_{\alpha r}, \phi_{\alpha i}]^T = \sum_{n=0}^N [\Phi_{\alpha r}^{(n)}, \Phi_{\alpha i}^{(n)}, \phi_{\alpha r}^{(n)}, \phi_{\alpha i}^{(n)}]^T (1-x^2)^2 T_n(x), \tag{34}$$

$$[\Theta_{\alpha r}, \Theta_{\alpha i}, \theta_{\alpha r}, \theta_{\alpha i}]^T = \sum_{n=0}^N [\Theta_{\alpha r}^{(n)}, \Theta_{\alpha i}^{(n)}, \theta_{\alpha r}^{(n)}, \theta_{\alpha i}^{(n)}]^T (1-x^2) T_n(x). \tag{35}$$

The normalization condition for the eigenfunction $\Phi_r^{(0)}=1$, $\phi_r^{(0)}=\Phi_i^{(0)}=\phi_i^{(0)}=0$ yields that $\Phi_{\alpha r}^{(0)}=\phi_{\alpha r}^{(0)}=\Phi_{\alpha i}^{(0)}=\phi_{\alpha i}^{(0)}=0$. Under this condition, we make use of the collocation method and eqs. (26)-(33) are reduced to an algebraic equation of the form of

$$B \mathbf{x} = \mathbf{b} , \quad (36)$$

again where B is now a $8(N+1) \times 8(N+1)$ -matrix, \mathbf{x} and \mathbf{b} are $8(N+1)$ -vectors, and \mathbf{x} has the component :

$$\begin{aligned} \mathbf{x} = & [c, \phi_r^{(1)}, \phi_r^{(2)}, \dots, \phi_r^{(N)}, \mathbf{g}^{-1}, \phi_i^{(1)}, \phi_i^{(2)}, \dots, \phi_i^{(N)}, \\ & \theta_r^{(0)}, \theta_r^{(1)}, \dots, \theta_r^{(N)}, \theta_i^{(0)}, \theta_i^{(1)}, \dots, \theta_i^{(N)}, \\ & c_{\alpha}, \phi_{\alpha r}^{(1)}, \phi_{\alpha r}^{(2)}, \dots, \phi_{\alpha r}^{(N)}, \alpha, \phi_{\alpha i}^{(1)}, \phi_{\alpha i}^{(2)}, \dots, \phi_{\alpha i}^{(N)}, \\ & \theta_{\alpha r}^{(0)}, \theta_{\alpha r}^{(1)}, \dots, \theta_{\alpha r}^{(N)}, \theta_{\alpha i}^{(0)}, \theta_{\alpha i}^{(1)}, \dots, \theta_{\alpha i}^{(N)}]^{T}. \end{aligned} \quad (37)$$

See Appendix B for further detail.

We have shown how to determine the critical condition. But in doing so, we need the initial guesses of $\partial\phi/\partial\alpha$ and $\partial c/\partial\alpha$ for the neutral modes. Suppose that M_1 iterations are necessary to get one neutral mode. Then $2M_1$ iterations are required to evaluate the values of the initial guesses. Moreover, we need M_2 iterations to obtain the critical condition. The total number of iterations are thus $2M_1+M_2$. Compare this value with $N_1 \times N_2$ mentioned at the beginning of this section. Values of N_1 , M_1 , and M_2 are usually almost the same (≤ 8) while N_2 is usually much greater than M_2 . We thus find the efficiency of the present method.

3. NUMERICAL RESULTS

The efficiency of the present method is demonstrated in this section by showing some numerical results. The first example is the critical condition for $m \rightarrow 0$. If $P < 12.7$, the critical condition is known to be given by stationary modes while the condition is given by traveling modes for $P > 12.7$ according to Korpela, Gözüüm, and Baxi,⁷ or Bergholz,⁵ for example. But more detailed evaluation by Chen & Pearlstein⁸ revealed recently that the critical value of P lays between 12.4 and 12.5. The critical Prandtl number problem is particularly important if we are interested in nonlinear interaction between the critical stationary mode and the critical traveling modes.

Numerical evaluation of the critical Grashof numbers for various values of the Prandtl number reveals that the critical Prandtl number is given by $P = 12.45425644$, which is consistent with Chen & Pearlstein's result. All the figures of this value are considered to be significant. Let us first show how fast the iteration of the Newton-Raphson method converges in Table 1, 2, 3, and 4 for this value of P .

The convergence of the expansion in Chebyshev polynomials is checked by changing N in eqs. (13), (14), (31), and (32). The results are demonstrated in Table 5.

Table 1 Convergence of the iteration to determine the traveling neutral mode. $N=50$, $P=12.45425644$, $\alpha=0.3$, and $m \rightarrow 0$.

Number of iterations is denoted as n .

Table 4 Convergence of the iteration to determine the critical condition for stationary modes. $N=50$, $P=12.45425644$, and $m \rightarrow 0$.

Number of iterations is denoted as n .

n	α	G	c
1	1.387915924402	488.5291653467	7.80×10^{-15}
2	1.383151658729	492.0452586859	1.59×10^{-17}
3	1.383147622284	492.0563331220	-7.65×10^{-19}
4	1.383147622728	492.0563331734	-7.50×10^{-19}
5	1.383147622728	492.0563331734	-3.10×10^{-18}

We can thus obtain 12 significant figures for the critical condition (α , G) with $N=50$. Changing the value of the Prandtl number, we determined its critical value as 12.45425644 at which the critical Grashof number for the stationary mode coincides with that for the traveling mode. We finally mention about CPU time taken by FACOM VP-100 computer and required memory size. It takes 7.89 sec. to get the critical condition for stationary mode with $N=50$ while 17.72 sec. is taken with $N=70$. It takes 10.16 sec. to get the critical condition for traveling modes with $N=50$ while 22.78 sec. is used with $N=70$. CPU times for stationary modes are different from those for traveling modes because of the difference upon the number of iteration. This calculation requires 6,836 KBytes memory size.

Let us now return back to the Orr-Sommerfeld equation (1) for parallel shear flows. Plane Poiseuille flow is a flow which has been investigated most extensively about its linear and nonlinear stability characteristics mainly based on the Orr-Sommerfeld systems. The critical condition has been evaluated repeatedly by different investigators asymptotically or numerically.² The well known critical condition was obtained by Orszag based on the expansion method in Chebyshev polynomials as $(\alpha, R, c)=(1.02056, 5772.22, 0.264002)$.⁹ This condition was, however, corrected by Davey as $(1.020547, 5772.2218, 0.2640003)$, [see ref. 2], and the validity of the latter condition was confirmed

Table 5 Convergence of the critical conditions with respect to the truncation level N in the expansion in Chebyshev polynomials. $P=12.45425644, m \rightarrow 0$.

50	1.383147622728	492.0563331734	0.3424110375336	492.0563332753	0.05959947420190
70	1.383147622729	492.0563331732	0.3424110375336	492.0563332753	0.05959947420190

by the present author¹⁰ : the critical wavenumber lays between 1.0205474 and 1.0205475 while the critical Reynolds number is given by 5772.2218. An usual solver for the eigenvalue problem cannot determine the critical wavenumber, critical Reynolds number, and the critical phase velocity beyond 8 significant figures as far as a double precision algorithm is utilized because the critical condition has to be determined based on a detailed information for c_i although $|c_i| / |c_r| \rightarrow 0$ as we approach the critical condition. The present method, on the other hand, is considered to be superior to the others because it assumes the critical condition $\partial G / \partial \alpha = c_i = 0$ from the beginning, exactly. We therefore need not discuss about precise values of c_i .

Modification of our numerical program for the critical condition of plane Poiseuille flow problem is quite straightforward : just neglect terms involving the temperature disturbances and neglect the disturbance equations for the temperature from eqs. (9)-(12) and (23)-(30). The obtained results are listed in Table 6 with different truncation level N in the Chebyshev expansions.

Table 6 Convergence of the critical conditions for plane Poiseuille flow with respect to the truncation level N in the expansion in Chebyshev polynomials.

4. CONCLUSIONS

We proposed the method to determine the critical condition on the linear stability of parallel shear flows. The critical conditions are assumed from the beginning there so that any numerical error associated with the value of small linear growth rate does not appear. We demonstrated the efficiency of the present method for two fundamental basic flows : the free convection between vertical parallel plates with different temperatures and the plane Poiseuille flow.

Notes added in proof:

Professor M. Takashima indicated that the same critical Prandtl number $12.4 < P_c < 12.5$ as the one by Chen & Pearlstein was obtained by M. Takashima and H. Hamabata [J. Phys. Soc. Jpn. 53 (1984) pp.1728-1736].

Appendix A NOTES ON THE PROGRAM

This program consists of MAIN, CRIT, NEUTRL, PARA, QR, MTRXC, NORMAL, MODE, EFUNC, CHEB1, CHEBY, MTRXPR, LUDCMP, LUBKSB, and VFLOW. Among them, LUDCMP and LUBKSE are copied from the excellent book '*Numerical Recipes*'.⁶ [(C) 1986 by Numerical Recipes Software. Reproduced by permission, from the book *Numerical Recipes: The Art of Scientific Computing*, published by Cambridge University Press.]

MAIN is a main program which control the computer algorithm.

PARA is called in order to get input data. IC controls an objective of the computation : IC=0 leads us to calculate the critical conditions for different values P at fixed value of m while IC=1 let a computer continue to calculate neutral conditions for different α at fixed pair of parameters (P, m). N denotes the maximum degree of Chebyshev polynomials N in (16), (17), (34), and (35). EM indicates m.

EFUNC makes a table for expansion functions and basic fields for fixed value of m. T1 and T2 are expansion functions $(1-x^2)^2 T_n(x)$ and $(1-x^2) T_n(x)$, respectively. T1 and T2 have arrays like (i, j, k). The i indicates an order of derivatives, j indicates the degree of Chebyshev polynomials, and k indicates a location of collocation points. U has arrays like (i, j) where i denotes an order of derivatives of W and j denotes the location of collocation points. The $T'(x_i)$ is given by U(3, j), exceptionally.

Usual eigenvalue problem, eqs. (4) and (5) subject to the homogeneous boundary conditions, have to be solved in a usual technique in order to get an initial guess for c, G, ϕ , and θ . The neutrality of the initial guess is not necessary. The following four subroutines are for this purpose.

MTRXC makes each component of matrices which are the final form of Chebyshev collocation method. If we expand ϕ and θ in Chebyshev polynomials as

$$\phi = \sum_{n=0}^N \phi^{(n)} (1-x^2)^2 T_n(x), \theta = \sum_{n=0}^N \theta^{(n)} (1-x^2) T_n(x),$$

then the resultant disturbance equations (4) and (5) at each collocation points are written concisely as $A\mathbf{x}=cB\mathbf{x}$ where A and B are $2(N+1) \times 2(N+1)$ matrices and \mathbf{x} is $2(N+1)$ -vector. MTRXC provides all the components of matrices A and B.

QR calls QR-subroutine package which is provided in each computer machine, individually. In the present program, $B^{-1}A$ is created by using a LU decomposition routine, a matrix inversion routine, and a product routine between two matrices. Then the eigenvalue of $B^{-1}A$ and associate eigenfunction are calculated by a QR-routine package provided in FACOM machine.

MODE rearranges the eigenvalues and associated eigenfunctions in order for the linear growth rate to satisfy an inequality $\alpha c_1^{(1)} > \alpha c_1^{(2)} > \alpha c_1^{(3)} > \dots > \alpha c_1^{(n+1)}$.

NORMAL makes the normalization of the eigenfunction so as to satisfy $\phi^{(0)} = 1$ and $\phi^{(n)} = 0$ for $n \neq 0$.

The above subroutines are called in order to obtain the initial guess for the finding procedure of the neutral mode. Now we have to calculate two neutral phase velocities and neutral eigenfunctions for two values of α , α_1 and α_2 which are very close to each other. Then we make initial guesses for c_α , ϕ_α , and θ_α .

NEUTRL is a subroutine to find the neutral condition following eqs. (12)-(19).

CRIT is a subroutine to find the critical condition following eqs. (26)-(37).

CHEB1 provides expansion functions $(1-x^2)^2 T_n(x)$ and $(1-x^2) T_n(x)$ and their derivatives up to 4-th order at each collocation points. Factors $(1-x^2)^2$ and $(1-x^2)$ are involved in order for the expansion functions to satisfy the homogeneous boundary conditions at $x = \pm 1$ for ϕ and θ .

CHEBY generates the Chebyshev polynomials $T_n(x)$ and their derivatives up to 4-th order at each collocation points.

VFLOW generates the basic flow profile, their 1st and 2nd derivatives and the 1st derivative of the temperature profile at each collocation points. The nondimensional temperature gradient m is involved as a parameter.

MTRXPR makes a product of matrices.

Appendix B PROGRAM LIST

Program list for FACOM computer is presented. We utilized DCLU, DCLUIV, and DCEIG2 subroutine packages from "SSL2" subroutine library installed in FACOM VP-100 in solving (1) and (2) to get the initial guesses.
