Abstract

This paper first reviews the history of irradiation treatment of sewage sludge in the world. First sludge irradiation plant was built in Geiselbullach, West Germany in 1973 which used ^{60}Co as irradiation source. Since then, many sludge irradiators were constructed in U.S.A., India, Japan, Canada, Poland and So on which used ^{60}Co , ^{137}Cs or electron beam as irradiation sources. Then the paper describes some basic research on irradiation treatment of sewage sludge including optimization of irradiation parameters, synergistic effect of radiation with heat, oxygenation, irradiation-composting and potential applications of treated sludge. Some proposals have been suggested for further development of this technology in the future.

Key Words: Sewage sludge, irradiation, γ -ray, electron beam.

1. Introduction

Sewage sludges are mainly from ground surface of city river and biochemical sediment after biochemical treatment of a variety of effluents, especially from puvalty farms. It represents a renewable resource of great economic significance. It has a high concentration of nitrogen and phosphorus and a wide spectrum of trace elements for efficient growth and yield of crops in agricultural practice. In addition, the high content of organic matter(15%) in sludge make it valuable in agronomic applications. Typical analysis of organic and trace element contents of sludge by Indian Scientists is shown in Table 1.

However, untreated sludge is a potential hazard to human health and environment as it contains a high concentration of pathogenic agents that include parasites, bacteria and viruses. Release of sewage sludge without disinfection into the environment have been shown to be responsible for the contamination of soil, food supplies and usable water resources. Conventional sludge processing techniques such as liming, aerobic and anaerobic treatment, composting, digestion etc do not provide adequate reduction in pathogens and particularly not effective in destroying the eggs of parasites. For instance, in the process of composting, bacterial oxidation results in elevated temperatures and this brings about a certain reduction in the pathogen content. The

Table 1. Typical Compositions of Liquid Digested Sludge

Dry matter content (D.M.)	4.30%
Organic Substance (% of D.M.)	50.00
Inorganic Substance (% of D.M.)	50.00
<u>Nutrients</u>	
Total-N (% of D.M.)	5.30

Na(ppm)	2000
Mn ~	200
Cu ~	370
Zn ~	300
Total organic carbon(% of D.M.)	15.2

resulting compost, however, has limited agriculture application. Thermal disinfection is an energy intensive process and is generally considered expensive. Treating sludge by irradiation promises a safe, efficient and controllable reduction in pathogen levels to give a sludge products that is highly useful in agriculture.

2. Summary on sewage sludge irradiation plants in the world:

The first sewage sludge irradiation plant in a technical scale was constructed in 1973 at Gesiselbullach, West Germany, where ⁶⁰Co was used as the source material (Fig.1). The plant was designed with a fully automatic operation during 24hrs and a high availability. In 1984, ¹³⁷Cs was added to the facility to supplement the existing ⁶⁰Co sources.

In the united states, a 7,250 kg/day (8 ton/day) irradiator was constructed in 1978 by Sandia National Laboratories in Albuquerque, New Mexico. At this facility, ¹³⁷Cs was used as the source material.(see Fig.2). In 1976, an electron beam irradiation system was put on-line at Boston's Metropolitan District Commission Wastewater Treatment plant at Dear Island. The facility handled up to 15.8m³/hr of liquid sludge, delivered a dose of 4 kGy and was primarily used for research purposes. Electrons were generated by a 750kV, 50kW commercial election accelerator. A 2mm thick sheet of sludge was irradiated as it passed over the top of a rotating stainless drum as shown in Fig.3. Unlike the γ irradiation in West Germany and New Mexico, a thin layer of sludge must be produced due to limited penetration capability of the electron beam. However, electron beam is much more efficient in power compared to γ -ray, because it has high ionization density and high treatment capacity.

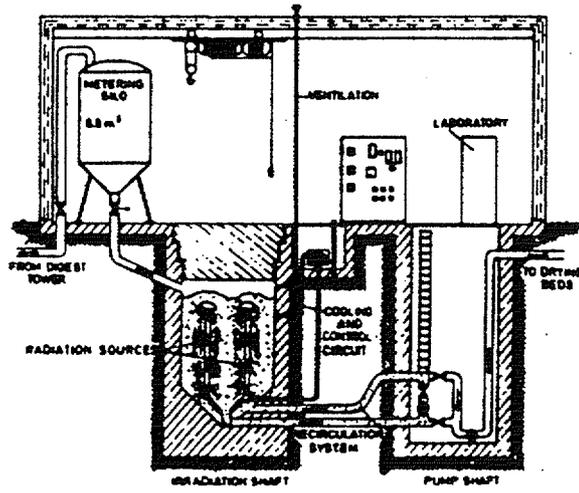

FIG. 1. Schematic of sludge irradiation plant in Geiselbullach, West Germany.

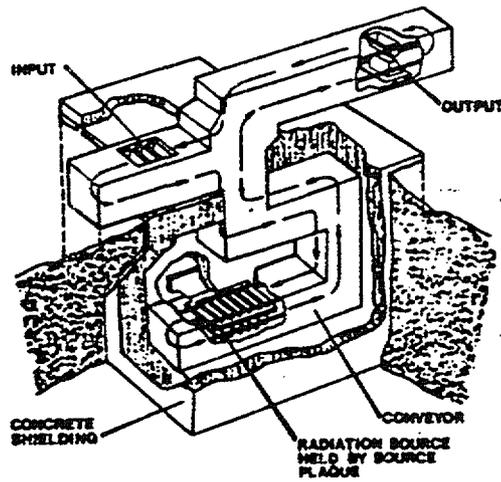

FIG. 2. Sandia Irradiation for Dried Sewage Solids (SIDSS), Albuquerque, New Mexico.

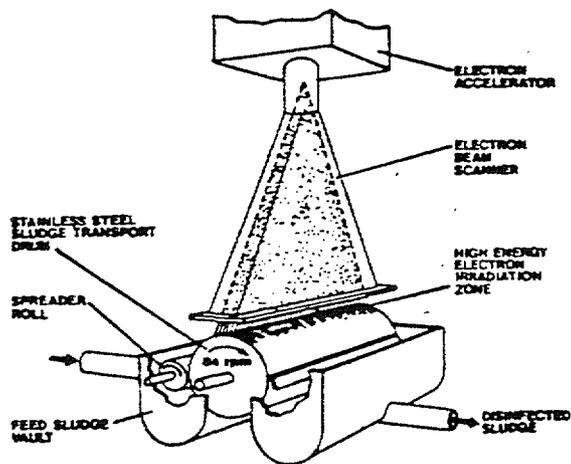

FIG. 3. Sludge irradiation process used at Dear Island Wastewater Treatment Plant near Boston, Massachusetts.

Based on Deer Island's experience, the Miami-Dade Water and Sewer Authority in Florida decided to locate a sludge irradiator using accelerated electrons at its Virginia Key Wastewater Treatment plant. This irradiator officially began operation in Sept. 1984. The electrons are accelerated to an energy of 1.5 MeV and directed to a maximum beam width of 1.2 m. The dose is 3.5 ~ 4 kGy. A thin layer is obtained by cascading the sludge over a weir-type arrangement, thus forming a curtain of sludge approximately 4 mm thick (Fig. 4). This sludge handling system has a flow of 27 m/hr and the sludge contains 2% dried solids. The installation at Virginia Key can treat 20 ~ 25% of the total sewage sludge produced at the plant. Space is provided to allow the setup of three more accelerators for expansion to the total sludge production. Irradiated sludge is conditioned with polymer and dewatered in centrifuges. The sludge is stored for several months to dry up. Ultimately, the sludge is screened and distributed for agricultural use.

In Japan, irradiation treatment of sewage sludge has mainly been carried out by Takasaki Radiation Chemistry Research Establishment, Japan Atomic Energy Research Institute. Fig. 5 shows an apparatus for electron beam irradiation. Sludge cake (water content 80%) is spreaded on a stainless steel conveyor through a flat nozzle and disinfected by electron beam which comes from upside of the apparatus. The width of the nozzle is 20 cm and sludge thickness is variable from 1 ~ 10 mm. The maximum feed rate is 300 kg/hr. The electron accelerator used for irradiation is of Cockcroft-Walton type. Its maximum beam energy and current are 2 MeV and 30 mA respectively.

The research on irradiation treatment of sewage sludge in India was mainly done by Bhabha Atomic Research Center (BARC) in Bombay. The pilot scale project was taken up by BARE in collaboration with local agents for setting up an irradiation treatment plant to be located at Baroda, a city in Western India. The features of irradiation treatment plant are shown in Table 2.

Table 2. Features of irradiation treatment plant proposed at Baroda, India

sludge processing rate (max.)	~	110 m ³ /day (4~6% solid)
treatment dose	~	3~3.5 kGy
pathogen reduction		
bacteria	~	6~7 log units
viruses	~	1 log units
installed activity (max.)	~	500 kCi
sources utilization period	~	20 years
shield design capacity	~	1 Mci
external radiation level	~	0.1 mr/h
provision to store and transfer source to a safe location.		

In Poland, electron beam irradiation of sewage sludge has been developed in recent years. In Otwork, an irradiation facility for accelerator irradiation of municipal

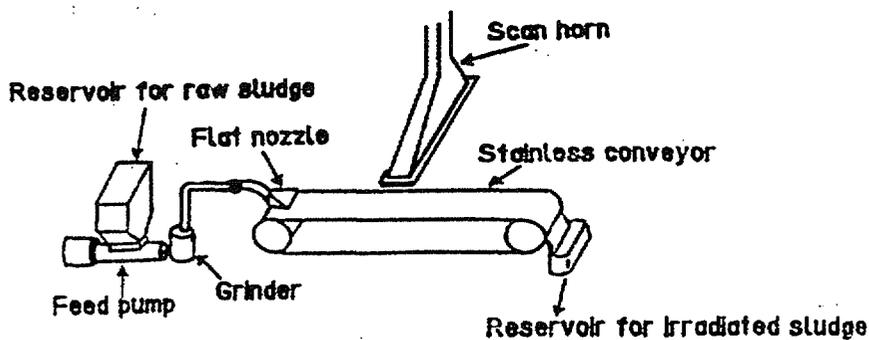

FIG. 5. Apparatus for electron beam irradiation of sludge.

sewage and sludge was built up with a dose of 5 kGy. Total investment is 4 million U.S. dollar. Daily treatment capacity is 48,000 m³ (30% solid content).

Irradiation treatment plants of sewage sludge have also been built up in some other countries in the world, for instance, Canada and so on.

3. Some basic research on irradiation treatment of sewage sludge

3.1. Optimization of parameters for radiation hygienisation.

Scott and Ahlstron from New Mexico, U.S.A. measured D-values (the absorbed dose of radiation required to reduce a population one order of magnitude) of selected sludge-borne pathogens. (Table 3)

Table 3. D-value of selected sludge-borne pathogens

Organism	D-value (kGy)
Bacterium	<0.22~0.36
<u>E. coli</u>	1.4
<u>Micrococcus sp.</u>	0.36~0.92
<u>Enterobacter sp.</u>	0.34~0.47
<u>Salmonella typhimurium</u>	<0.50~1.40
<u>Proteus mirabilis</u>	<0.22~0.5
<u>Streptococcus faecalis</u>	1.10~2.50
Viruses	1.5~5.0
Poliovirus	3.5
Coxsackievirus	2.0
Echovirus	1.7
Reovirus	1.65
Adenovirus	1.50
Parasites	
<u>Ascaris sp.</u>	<0.66
Fungi	
<u>Aspergillus fumigatis</u>	0.5~0.6

In china, research was done on irradiation treatment of hospital sewage sludge. Beijing Institute of Environment Protection together with Beijing Tuberculosis Hospital had investigated the radiation sterilization of the sewage and sludge from Beijing Tuberculosis Hospital during 1978~1980. Table 4 shows the experimental results for minimum radiation lethal dose of various bacteria. The irradiation system for irradiation sterilizing hospital sewage and sludge on the basis of experimental date had been designed by Beijing Institute of Nuclear Engineering.

Table 4. Minimum radiation lethal dose of various bacteria in sewage and sludge from tuberculosis hospital (kGy)

Bacteria	physiological saline	sewage	sludge
ascaris eggs	0.8	0.8	1.2
E.coil	0.5	1.28	1.7
typhoid bacillus	1.0	--	1.5
dysentery bacillus	0.5	--	1.5
enterobacter aerogenes	0.5	--	1.0
bovine tuberculosis	0.4	1.0	2.0
attenualed tuberculosis human	1.0	2.0	2.0
tuberculosis enriched human	1.0	--	3.0
M.phlei	1.63	2.13	4.0

3.2. Synergistic effect of irradiation with other methods.

Lessel from Germany investigated the synergistic effect of heat, oxygen, air with irradiation. The most important findings are summarized here.

1) Combination treatment of heat/irradiation: When ova from the parasite *Ascaris Inbricoides* were placed in 47°C deionized water for 2 hrs, they remained stable. With ionizing irradiation, a D-Value of about 0.2 kGy was seen. Combining 47°C heat and radiation yields a D-value of about 0.1kGy.

2) Combination treatment of oxygenation/irradiation: At a dose of 1 kGy, it was found that the inactivation rate was 15 to 38 times higher at an oxygenation concentration of 5mg/l compared with irradiation without oxygenation. Higher concentration of oxygen in the sludge (15 to 25mg/l) did not increase the level of disinfection. An oxygenation treatment with a dose of 0.15~0.2 kGy has at least the same effect as 0.3 kGy of irradiation without oxygenation. It is 2 or 3 times more efficient to maintain the O₂ concentration in the sludge by continuous injection of oxygen at a low flow rate than intermittent injection at a higher flow rate.

3) The comparison between γ -ray and electron beam irradiation: The effect of γ -ray and electron beam irradiation are similar. However, electron beam has the advantage of high ionization density, high dose rate, high treatment capacity and high safety. So electron beam might be better choice for sludge irradiation compared with γ -ray. Japanese scientists investigated the effect of beam energy and sludge thickness on surviving fraction of total bacteria and coliforms (fig.6). It shows that, to kill bacteria effectively, sludge thickness must be less than 6 mm for beam energy of 2 MeV and 3mm for 1MeV.

4) Irradiation-composting: Japanese scientists from Takasaki Radiation Chemistry Research Establishment, JNERI evaluated the economic feasibility of irradiation-composting plant of sewage sludge. Design and cost analysis were made for a sewage sludge treatment plant (capacity of 25~200 ton sludge/day) with an electron accelerator. The flowsheet and bird's views of the plant is shown in Fig.7.

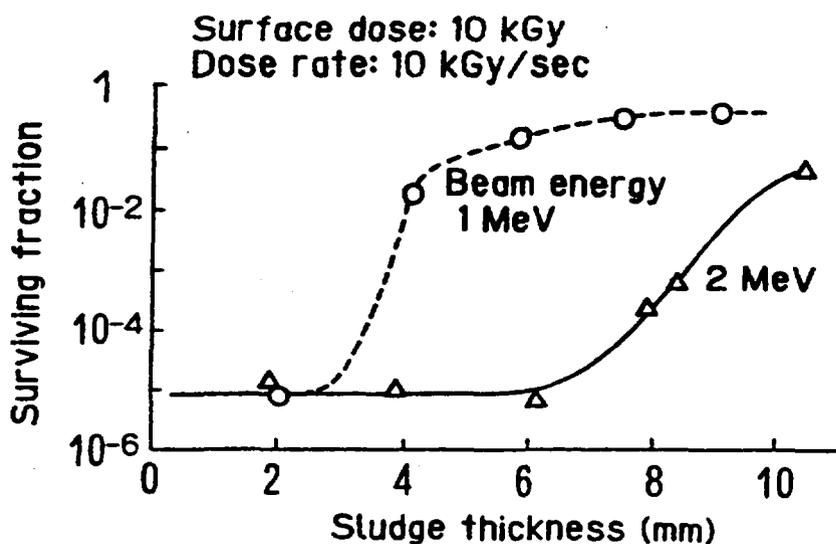

FIG. 6. Surviving fraction vs. sludge thickness.

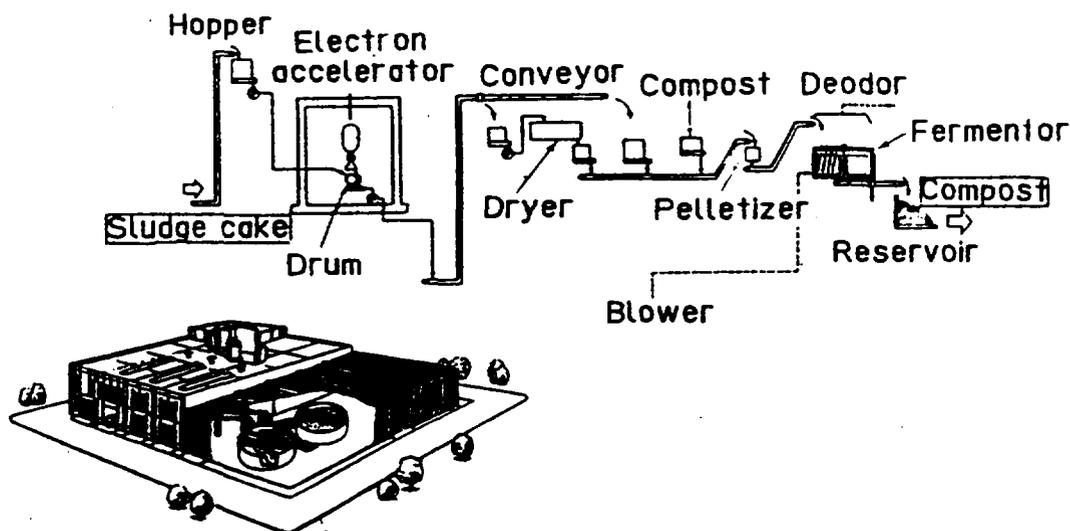

FIG. 7. Flow sheet and bird's view of the plant.

Dewatered sludge is spread on a rolling drum through a flat nozzle and disinfected by electron irradiation with a dose of 5kGy. The accelerating voltage of electron and capacity of the accelerator are 1.5MeV and 15kW respectively. Composting of the irradiated sludge is also made at the optimum temperature (about 50°C) for 3 days (conventional composting needs 10~12 days). Total volume of the fermentor is about 1/3 of that of conventional composting process because the irradiation makes the time of composting shorter. From the cost analysis, it shows that the capital cost of irradiation-composting plant is slightly less than conventional composting plant, when the treatment capacitor is larger than 50 ton/day. Total capacity cost of irradiation-composting plant is lower especially for large treatment plant because the scale of fermentor is 3 or 4 times smaller. So further research and development would be conducted in Japan using scale pilot plant of 200~300 ton/day capacity.

4. Potential applications of irradiated sludge

Untreated, irradiated and pasteurized sludge were used in agricultural pot and field experiments by German scientists. However, no statistical significant differences were observed in yield, while coin, spring wheat and spring burley were used. In India, properly treated sludge has vast potential applications, especially in agriculture as a complementary product -- as a soil conditioner, for augmenting the efficiency of utilization of chemical fertilizers and in animal husbandry as supplementary animal feed, because the Indian economy is still largely based on agriculture and animal husbandry.

A. Soil conditioner: The soils get depleted of organic matter through a variety of natural processes, especially in tropical area like India. The high temperature and humidity is suited for the accelerated growth of bacterial population in soil. These bacterial derive energy for their growth from organic matter in soil thus degrading the

soil the year round. Frequent and regular addition of organic matter to the soil is therefore very important to maintain and upgrade the soil fertility and crop production. Sludge forms a natural soil conditioner of excellent qualities.

B. Fertilizer complement: Chemical fertilizers when combined with sludge will serve as an optimum product for agricultural application. The cultivation of high yielding crops to improve productivity has intensified the application of chemical fertilizers on a large scale. These, however, quickly deplete the soil of organic and micronutrients. Further the uptake of nutrients such as nitrogen, phosphorus etc. from the fertilizer has also been found dependent on various factors, including the carbon balance or organic content soil. Extensive studies (Dhua, 1979; Sekar, 1981) have shown that uptake is generally between 30-50% even when the best management practices are employed. One way to reduce this waste is to employ an organic-mineral mixture of sludge and chemical fertilizer in a suitable ratio which retains advantages of both and saves on the cost of a part of the chemical fertilizer. This is of considerable economic value to developing countries where fertilizers are often imported. Further with the escalating fertilizer costs, the need for a composite product - organic manure with mineral fertilizers has become imperative. Another advantage is the reduction in pollution to the groundwater, as often the unutilised fertilizer nitrates are leached into water by infiltration and surface run-off.

C. Animal feed: The use of sludge as animal feed has a great potential. the waste from any town could meet part of its ruminant feed requirements from sewage sludge suitably disinfected.

5. Some proposal for irradiation treatment of sludge in Shanghai

Shanghai is a big city in China. Suzhou river is a main river across the city. However, serious contamination by industrial and municipal wastes makes the river dark and very bad smell. The sludges from Suzhou river and biochemical sludge from waste water treatment plant present a big problem in treatment. We suggest a proposal for irradiation treatment of sewage sludge mainly from Suzhou river. The outline of the proposal is as follows:

1. Basic research on irradiation of sewage sludge from Suzhou river including component analysis (organic substances, nutrients, trace elements, variety of bacteria), optimization of parameters for irradiation hygienbization (the comparison between γ -ray and electron beam, synergistic effect of irradiation and other methods) and comprehensive treatment (irradiation + composting, irradiation + sediment, et al)
2. Technological research including flowsheet design and accelerator manufacture. We proposed that a accelerator with electron of 1.5MeV, 30mA should be manufactured. If the water content of the sludge is 50% and the dose is 3~5kGy, the capacity could be 50~100 ton/day.
3. The application of irradiated sludge: As mentioned above, it could mainly be used as composite fertilizer, soil conditioner and animal feed. We prefer its application in agriculture.

6. Summary

1. Sewage sludge represents a renewable resource of great economic significance. However, untreated sludge is a potential hazard to human health and environment as it contains a variety of pathogenic agents.
2. Research over past thirty years has demonstrated that irradiation (γ -ray and electron beam) is an effective means for inactivating pathogens in sewage sludge. Further research and development will be focused on development of appropriate technologies for irradiation plants and estimation of capital cost and treatment cost more precisely.
3. The synergistic effect of irradiation with other methods (heat, oxygen, et al) has been found. It could enhance the treatment efficiency and reduce the treatment cost.
4. Research has demonstrated a vast potential applications of treated sludge, particularly in agriculture as soil conditioner and fertilizer complement and in animal husbandry as supplementary animal feed.
5. A proposal is put forward for irradiation treatment of sludge from Suzhou river of Shanghai.
