Abstract

The paper presents the main aspect concerning the electric parameter variation of jointing clamps operating under specific environmental conditions determinate by pressure, temperature and humidity.

The testing of jointing clamps capability to meet and exceed the required performances all along its operating life implies the performing of LOCA simulation conditions while the jointing clamps is bright in a relatively short time under conditions equivalent to those at the end of its service life.

The paper describes ageing and measurement techniques and the analyses of electric parameter behaviour in these environmental simulated conditions.

Key words:

Jointing clamps, Parameters variations
